

AI Usage Note — Fulfillment Hub

Purpose of AI Usage

AI was used as a supporting tool during the development of the Fulfillment Hub prototype. The purpose was to improve productivity during ideation, prototyping, documentation and review while keeping the final business decisions and solution direction under my own judgment.

How AI Was Used

AI was used for the following activities:

- Brainstorming and structuring the fulfillment workflow based on the assignment requirements.
- Identifying potential operational problems and helping organize them by priority.
- Creating realistic dummy data for orders, products, inventory, issues and shipments.
- Supporting the implementation of the browser-based prototype.
- Helping with debugging and improving the user interface during development.
- Reviewing and improving the wording of the project documentation and walkthrough script.

My Own Judgment and Decisions

I reviewed and adapted the AI-generated suggestions based on the actual scenario described in the assignment.

1. Prioritizing operational problems

I focused the solution on four key areas:

- Order status visibility
- Priority and at-risk order management
- Inventory exceptions between the main and secondary warehouse
- Warehouse handoffs, issues and courier pickup

These were selected because they have a direct impact on fulfillment delays, missed deadlines and operational errors.

2. Keeping the workflow simple

AI suggested that different user groups could have separate dashboards. I decided to use a shared operational workflow because the scenario involves a small office and warehouse team. This keeps the application easier to understand and reduces unnecessary navigation.

3. Focusing on actionable information

Rather than displaying a large number of metrics, I selected a small set of operational indicators such as Orders Today, Priority Orders, At Risk Orders, Open Issues and Ready for Pickup.

The objective was to help the team quickly identify what requires attention rather than simply providing more data.

4. Inventory exception handling

I used the scenario of an order where the required stock is available in the secondary warehouse but not in the main warehouse. The solution highlights this exception and provides a transfer action before picking, reflecting the operational requirement that stock must be moved to the main warehouse first.

Final Approach

The final prototype is designed as a lightweight fulfillment operations tool rather than a complex enterprise system. It focuses on visibility, exception management and clear warehouse handoffs.

AI was therefore used as a productivity and implementation-support tool, while the final prioritization, workflow decisions and operational approach were reviewed and selected from an Operations Analyst / Business Analyst perspective.
